## **THIS IS ONLY A PROTOTYPE**

by Andrea G.B. DAMIOLI

The AEgIS Experiment at the CERN aims to verify the weak interaction principle for antimatter. This document talks about "gAnWeb", a web application designed to simplify the analysis of physical data under the AEgIS experiment. This analysis can be performed using Root Data Analysis Framework by the Linux Terminal, but a graphical interface can ensure a better user experience, eases the user training and improves the productivity. A web application is a smart way to implement the interface because allows users to avoid installations, and centralizes all the eventual modifications. This document explains the choices made during the development of this application, related to the goal of the data analysis.

# Chapter 1

## Introduction

First of all is important to understand at least generically what is the AEgIS experiment at the CERN and what are their goals. The acronym AEgIS stands for "Antimatter Experiment: gravity, Interferometry, Spectroscopy", this experiment aims to measure weak equivalence principle for antimatter. In this first chapter are explained some particular about this experiment.

### 1.1 AEgIS experiment

The logo for the AEgIS experiment, consisting of the letters A, E, g, I, and S in a large, black, serif font. The letter 'g' is stylized with a horizontal bar over it, representing the Greek letter gamma ( $\bar{g}$ ).

FIGURE 1.1: AEgIS's Logo

The weak equivalence principle, also known as universality of free fall, states that in the same field all bodies fall with the same acceleration, regardless of the mass and the composition. This principle has been thoroughly tested for the matter, but not for the antimatter: the most important goal of AEgIS experiment is to measure the weak equivalence principle for the anti-matter; to test this principle AEgIS measures gravitational interaction between matter (the earth) and anti-matter (anti-hydrogen). In the context of neutral antimatter, the gravitational interaction is of high interest, because it can potentially revealing new forces that violate the weak equivalence principle. Thomas Phillips, from Duke University, says: "If antimatter fell down faster, it would mean the discovery of at least one new force,

probably two. If it fell up, it would mean our understanding of general relativity is incorrect". In a practical point of view AEgIS tries to measure the time of flight and the vertical displacement of antihydrogen, by a moiré deflectometer: this process is shown in the image [TODO INSERT-THE-NUMBER-OF-THE-IMAGE].
